Joint work with Daniel Li (BMS), Ruitao Lin (MD Anderson), Bo Huang (Pfizer), and Ying Yuan (MD Anderson)

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Background – Project Optimus

- In 2022, FDA initiated Project Optimus “to reform the dose optimization and dose selection paradigm in oncology drug development.”
- Paradigm shifting from **maximum tolerated dose (MTD)** to **optimal biological dose (OBD)**.

Conventional Chemotherapy

Targeted Therapies

- MTD-based dose finding is often appropriate to inform RP2D
- Safety alone is not sufficient to inform optimal RP2D

Design and Sample Size Determination for Multi-Dose Randomized Trial

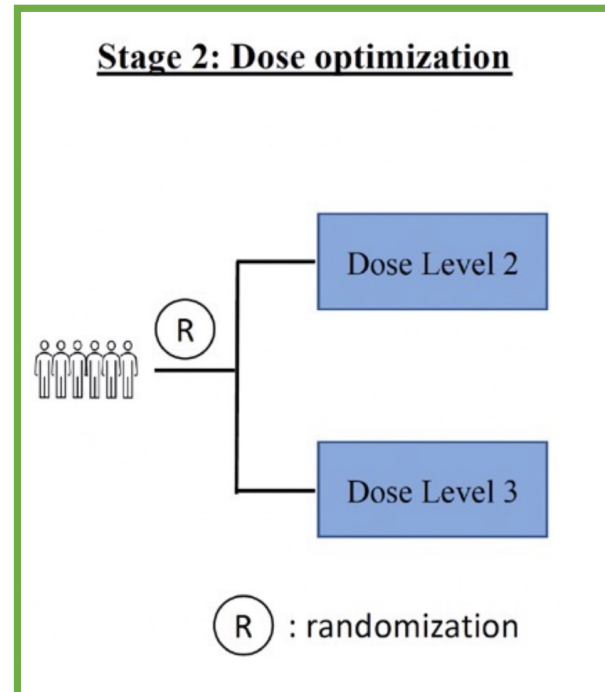

↳ Background – Design strategies to find OBD

- Trial designs to compare multiple dosages (FDA, 2023)
 - The trial should be sized to allow for sufficient assessment of activity, safety, and tolerability for each dosage.
 - The trial does not need to be powered to demonstrate statistical superiority of a dosage or statistical non-inferiority among the dosages

Stage 1: Dose escalation

Stage 2: Dose optimization

- MTD-based dose finding is often appropriate

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Background – Two-stage decision-making paradigm

1

Determination of OBD admissible dose set

- The objective is to identify a dose set that satisfy certain safety and efficacy requirements (i.e., OBD admissible set **A**).

2

Identification of the OBD

- The OBD will be selected from A based on the totality of activity, safety and tolerability data.
 - “Relevant nonclinical and clinical data, as well as the dose- and exposure- response relationships for safety and efficacy should be evaluated to select a dosage(s) for clinical trial(s)” (FDA guidance)
 - Unlikely/impossible to formulate statistical decision rules to capture all quantitative and qualitative considerations relevant to the final OBD selection

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Background – Two-stage decision-making paradigm

1

Determination of OBD admissible dose set

- The objective is to identify a dose set that satisfy certain safety and efficacy requirements (i.e., OBD admissible set **A**).

Goal: formulize the deign in this step to ensure the trial satisfies certain statistical properties, including type I error and power.

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Statistical modelling – set ups

- Consider a multiple-dose randomized trial, where a total of $J \times n$ patients are equally randomized to J doses, $d_1 < d_2 < \dots < d_J$.
 - In most applications, $J = 2$ or 3 , and d_J is often the MTD or maximum administered dose.

- Let Y_T and Y_E denote the binary toxicity and efficacy endpoints, respectively.
 - Example of Y_T : dose-limiting toxicity, dichotomized total toxicity burden.
 - Example of Y_E : objective responses, efficacy surrogate endpoints.

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Statistical modelling – assumptions

- Let $\pi_{T,j} = \Pr(Y_T = 1|d_j)$ and $\pi_{E,j} = \Pr(Y_E = 1|d_j)$ denotes the probability of the occurrence of toxicity and efficacy events.
- Assuming that $\pi_{T,j}$ and $\pi_{E,j}$ are **non-decreasing** with respect to the increasing of dose levels.
 - Randomized dose optimization trials have the same drug but with **ordered doses**
- For toxicity endpoint, we assume
 - $\phi_{T,0}$: the **null toxicity** rate that is **high** and deemed unacceptable;
 - $\phi_{T,1}$: the **alternative toxicity** rate that is **low** and deemed acceptable;
- For efficacy endpoint, we let
 - $\phi_{E,0}$: the **null efficacy** rate that is **low** and deemed unacceptable;
 - $\phi_{E,1}$: the **alternative efficacy** rate that is **high** and deemed acceptable

OBD admissible

| $\pi_{E,j}$ | | $\phi_{E,0}$ | $\phi_{E,1}$ |
| | |  |  |
| | |  |  |

Design and Sample Size Determination for Multi-Dose Randomized Trial

Statistical modelling – global type I error

- Consider H_0 : None of the doses is the OBD.
 - Challenge:** consists of multiple hypotheses ($\sum_{j=1}^{J+1} j$).

$$H_0(s, k) : \underbrace{\pi_{T,1} = \pi_{T,2} = \dots = \pi_{T,s} = \phi_{T,1}}_{\text{acceptable toxicity}} < \underbrace{\pi_{T,s+1} = \dots = \pi_{T,k} = \pi_{T,k+1} = \dots = \pi_{T,J} = \phi_{T,0}}_{\text{unacceptable toxicity}};$$

$$\underbrace{\pi_{E,1} = \pi_{E,2} = \dots = \pi_{E,s} = \pi_{E,s+1} = \dots = \pi_{E,k} = \phi_{E,0}}_{\text{unacceptable efficacy}} < \underbrace{\pi_{E,k+1} = \dots = \pi_{E,J} = \phi_{E,1}}_{\text{acceptable efficacy}},$$

where $s, k \in \{0, 1, \dots, J\}$ with $s \leq k$.

| | | d_1 | d_2 | | | d_1 | d_2 |
|------------|-----|--------------|--------------|------------|-----|--------------|--------------|
| $H_0(0,0)$ | Tox | $\phi_{T,0}$ | $\phi_{T,0}$ | $H_0(0,0)$ | Tox | $\phi_{T,1}$ | $\phi_{T,0}$ |
| | Eff | $\phi_{E,1}$ | $\phi_{E,1}$ | | Eff | $\phi_{E,0}$ | $\phi_{E,1}$ |
| $H_0(0,1)$ | Tox | $\phi_{T,0}$ | $\phi_{T,0}$ | $H_0(0,1)$ | Tox | $\phi_{T,1}$ | $\phi_{T,0}$ |
| | Eff | $\phi_{E,0}$ | $\phi_{E,1}$ | | Eff | $\phi_{E,0}$ | $\phi_{E,0}$ |
| $H_0(0,2)$ | Tox | $\phi_{T,0}$ | $\phi_{T,0}$ | $H_0(0,2)$ | Tox | $\phi_{T,1}$ | $\phi_{T,1}$ |
| | Eff | $\phi_{E,0}$ | $\phi_{E,0}$ | | Eff | $\phi_{E,0}$ | $\phi_{E,0}$ |

Design and Sample Size Determination for Multi-Dose Randomized Trial

Statistical modelling – global type I error

- Consider H_0 : None of the doses is the OBD.
 - Challenge:** consists of multiple hypotheses ($\sum_{j=1}^{J+1} j$).

$$H_0(s, k) : \underbrace{\pi_{T,1} = \pi_{T,2} = \cdots = \pi_{T,s} = \phi_{T,1}}_{\text{acceptable toxicity}} < \underbrace{\pi_{T,s+1} = \cdots = \pi_{T,k} = \pi_{T,k+1} = \cdots = \pi_{T,J} = \phi_{T,0}}_{\text{unacceptable toxicity}};$$

$$\underbrace{\pi_{E,1} = \pi_{E,2} = \cdots = \pi_{E,s} = \pi_{E,s+1} = \cdots = \pi_{E,k} = \phi_{E,0}}_{\text{unacceptable efficacy}} < \underbrace{\pi_{E,k+1} = \cdots = \pi_{E,J} = \phi_{E,1}}_{\text{acceptable efficacy}},$$

where $s, k \in \{0, 1, \dots, J\}$ with $s \leq k$.

- Define *global type I error* that encompasses all $H_0(s, k)$ as follows:

$$\begin{aligned} \alpha &= \Pr(\text{reject } H_0 | H_0) \\ &= \max_{0 \leq s \leq J, s \leq k \leq J} \{\alpha(s, k)\}. \end{aligned}$$

where $\alpha(s, k) = \Pr(\text{reject } H_0(s, k) | H_0(s, k))$.

Design and Sample Size Determination for Multi-Dose Randomized Trial

Statistical modelling – generalized powers

- Consider H_1 : At least one does is the OBD admissible.

- Challenge:** consists of multiple hypotheses ($\sum_{j=1}^J j$).

$$H_1(u, v) : \underbrace{\pi_{T,1} = \pi_{T,2} = \dots = \pi_{T,u} = \pi_{T,u+1} = \dots = \pi_{T,v} = \phi_{T,1}}_{\text{acceptable toxicity}} < \underbrace{\pi_{T,v+1} = \dots = \pi_{T,J} = \phi_{T,0}}_{\text{unacceptable toxicity}};$$

$$\underbrace{\pi_{E,1} = \pi_{E,2} = \dots = \pi_{E,u} = \phi_{E,0}}_{\text{unacceptable efficacy}} < \underbrace{\pi_{E,u+1} = \dots = \pi_{E,v} = \pi_{E,v+1} = \dots = \pi_{E,J} = \phi_{E,1}}_{\text{acceptable efficacy}},$$

where $u, v \in \{0, 1, \dots, J\}$ with $u < v$.

| | | d_1 | d_2 |
|------------|-----|--------------|--------------|
| $H_1(0,1)$ | Tox | $\phi_{T,1}$ | $\phi_{T,0}$ |
| | Eff | $\phi_{E,1}$ | $\phi_{E,1}$ |
| $H_1(0,2)$ | Tox | $\phi_{T,1}$ | $\phi_{T,1}$ |
| | Eff | $\phi_{E,1}$ | $\phi_{E,1}$ |
| $H_1(1,2)$ | Tox | $\phi_{T,1}$ | $\phi_{T,1}$ |
| | Eff | $\phi_{E,0}$ | $\phi_{E,1}$ |

 : OBD admissible

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Statistical modelling – generalized powers

- Consider H_1 : At least one does is the OBD admissible.
 - **Challenge**: consists of multiple hypotheses ($\sum_{j=1}^J j$).
 - **Additional challenge**: the standard definition of power, which reject the H_0 , is not sufficient to account for the characteristics of dose optimization.

| | | d_1 | d_2 |
|------------|-----|--------------|--------------|
| $H_1(0,1)$ | Tox | $\phi_{T,1}$ | $\phi_{T,0}$ |
| | Eff | $\phi_{E,1}$ | $\phi_{E,1}$ |
| | | ✓ | |
| Selection | | | ✓ |
| | | ✓ | ✓ |

- It is important to account for the quality of the admissible dose selection!

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Statistical modelling – generalized powers

- *Generalized power I:*

$$\beta_1(u, v) = \Pr \left(\begin{array}{c} \text{reject } H_0 \text{ and all dose in } A \text{ are truly} \\ \text{safe and efficacious} \end{array} \mid H_1(u, v) \right).$$

where A denotes the admissible dose set selected by the design.

- *Generalized power II:*

$$\beta_2(u, v) = \Pr \left(\begin{array}{c} \text{reject } H_0 \text{ and at least one dose in } A \text{ are truly} \\ \text{safe and efficacious} \end{array} \mid H_1(u, v) \right).$$

| | β_1 | β_2 |
|-------------------------|-----------|-----------|
| Tolerate false positive | ✗ | ✓ |

- Both generalized powers are stricter than the standard power.
- The choice of power depends on the characteristics of the trial and user's tolerability of false positive.
- Power II is a good option when reducing the sample size is of top priority.

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Statistical modelling – generalized powers

- Consider H_1 : At least one does is the OBD admissible.

- Challenge:** consists of multiple hypotheses ($\sum_{j=1}^J j$).

$$H_1(u, v) : \underbrace{\pi_{T,1} = \pi_{T,2} = \cdots = \pi_{T,u} = \pi_{T,u+1} = \cdots = \pi_{T,v} = \phi_{T,1}}_{\text{acceptable toxicity}} < \underbrace{\pi_{T,v+1} = \cdots = \pi_{T,J} = \phi_{T,0}}_{\text{unacceptable toxicity}};$$

$$\underbrace{\pi_{E,1} = \pi_{E,2} = \cdots = \pi_{E,u} = \phi_{E,0}}_{\text{unacceptable efficacy}} < \underbrace{\pi_{E,u+1} = \cdots = \pi_{E,v} = \pi_{E,v+1} = \cdots = \pi_{E,J} = \phi_{E,1}}_{\text{acceptable efficacy}},$$

where $u, v \in \{0, 1, \dots, J\}$ with $u < v$.

- We define *global power I and power II* that encompasses all $H_1(u, v)$ as follows

$$\beta_i = \min_{u, v \in \{0, \dots, J\}, u < v} \beta_i(u, v), \text{ for } i = 1, 2.$$

Design and Sample Size Determination for Multi-Dose Randomized Trial

Statistical modelling – least favorable set

Theorem 1. Define the least favorable set $\tilde{H}_1 = \{H_1(j), j = 1, \dots, J\}$, where

$$H_1(j) = \left(\underbrace{\pi_{T,1} = \dots = \pi_{T,j-1} = \phi_{T,1}}_{\text{safe but futile}} \quad \underbrace{\pi_{T,j} = \phi_{T,1}}_{\text{safe and efficacious}} \quad \underbrace{\pi_{T,j+1} = \dots = \pi_{T,J} = \phi_{T,0}}_{\text{toxic and efficacious}} \right).$$

For any $H_1(u, v)$, with $u, v \in \{0, 1, 2, \dots, J\}$ and $u < v$, there exists an $H_1(j)$ such that $\beta_i(j) \leq \beta_i(u, v)$, $i = 1, 2$, where $\beta_1(j)$ and $\beta_2(j)$ denote the generalized power I and II under $H_1(j)$, respectively.

- The global power can be equivalently defined as follows

$$\beta_i = \min_{j \in \{1, \dots, J\}} \beta_i(j) \text{ for } i = 1, 2.$$

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ MERIT Design

- MERIT (Multiple-dose Randomized Phase-II Trial)
 - Specify target global type I error α^* and power β^* ;
 - Randomize $J \times n$ patients equally to J dosing arm;
 - In any dose arm d_j , if $n_{E,j} \geq m_E$ and $n_{T,j} \leq m_T$, we reject H_0 and claim that d_j is OBD admissible, where m_T and m_E are decision boundaries for toxicity and efficacy, respectively.

* $n_{E,j}$ and $n_{T,j}$ are the total number of patients who experience efficacy and toxicity events in dose arm d_j .

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Optimal Design Parameters

- The optimal design parameters (n, m_T, m_E) are determined through numerical search such that the design controls the global type I error and power at nominal values α^* and β^* .

- Type I error

$$\begin{aligned}\alpha(s, k) &= \Pr(\text{reject } H_0(s, k) | H_0(s, k)) \\ &= 1 - \left\{ \left(1 - \Pr(n_T \leq m_T, n_E \geq m_E; n, \phi_{T,1}, \phi_{E,0}) \right)^s \right. \\ &\quad \times \left(1 - \Pr(n_T \leq m_T, n_E \geq m_E; n, \phi_{T,0}, \phi_{E,0}) \right)^{k-s} \\ &\quad \left. \times \left(1 - \Pr(n_T \leq m_T, n_E \geq m_E; n, \phi_{T,0}, \phi_{E,1}) \right)^{J-k} \right\}.\end{aligned}$$

- Power

$$\begin{aligned}\beta_1(j) &= \Pr(n_{E,1} < m_E, \dots, n_{E,j-1} < m_E, n_{T,j+1} > m_T, \dots, n_{T,j} > m_T, \\ &\quad n_{E,j} \geq m_E, n_{T,j} \leq m_T | H_1(j)), \\ \beta_2(j) &= \Pr(n_{E,j} \geq m_E, n_{T,j} \leq m_T | H_1(j))\end{aligned}$$

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Practice Consideration

- In small samples, isotonic transformed $\{\tilde{n}_{T,j}, \tilde{n}_{E,j}\}$ should be applied before comparing with boundaries (m_T, m_E) when non-decreasing assumption is sound for toxicity and efficacy.
- In some trials, it maybe desirable to add futility and safety interim monitoring
 - Stop arm j for safety if $\Pr(\pi_{T,j} > \phi_{T,1} | \text{data}) > C_T$,
 - Stop arm j for futility if $\Pr(\pi_{E,j} < \phi_{E,1} | \text{data}) > C_E$,
where C_T and C_E are probability cutoffs (e.g. 0.95).
- Whether to including interim monitoring depends on the availability of Y_T and Y_E , and other considerations. Typically, one or two interims are sufficient.

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Optimal Design Parameters

- Optimal design parameters (n, m_T, m_E) of MERIT design, when $J = 2$, $(\phi_{T,0}, \phi_{T,1}) = (0.4, 0.2)$, and $(\phi_{E,0}, \phi_{E,1}) = (0.2, 0.4)$.

Design Description

In this trial, the toxicity rates of 0.4 and 0.2 are considered unacceptable and acceptable, respectively, while the efficacy rates of 0.2 and 0.4 are considered unacceptable and acceptable, respectively. In order to control the global Type I error rate at 0.2 and achieve a global generalized power I of 0.8, a minimum sample size of 44 per arm is required. The generalized power I is defined as the probability of rejecting the null hypothesis that none of the doses are considered optimal biological doses (OBD) admissible and all doses identified as OBD admissible are truly safe and efficacious given the alternative hypothesis that at least one dose is OBD admissible. At the end of the trial, perform isotonic regression on toxicity and efficacy data across all doses. A dose will be considered OBD admissible if the isotonicly transformed number of toxicity ≤ 13 and the isotonicly transformed number of efficacy ≥ 13 .

Design Description

In this trial, the toxicity rates of 0.4 and 0.2 are considered unacceptable and acceptable, respectively, while the efficacy rates of 0.2 and 0.4 are considered unacceptable and acceptable, respectively. In order to control the global Type I error rate at 0.2 and achieve a global generalized power I of 0.8, a minimum sample size of 45 per arm is required. The generalized power I is defined as the probability of rejecting the null hypothesis that none of the doses are considered optimal biological doses (OBD) admissible and all doses identified as OBD admissible are truly safe and efficacious given the alternative hypothesis that at least one dose is OBD admissible. At the end of the trial, perform isotonic regression on toxicity and efficacy data across all doses. A dose will be considered OBD admissible if the isotonically transformed number of toxicity ≤ 13 and the isotonically transformed number of efficacy ≥ 13 .

During the trial, the toxicity and efficacy of each dose arm will be monitored independently using the stopping criteria outlined in Table 1. If the isotonically transformed toxicity and efficacy across topping boundaries, enrollment in that particular dose arm will be suspended.

Design and Sample Size Determination for Multi-Dose Randomized Trial

↳ Discussion

- In this project, we proposed a MERIT design for dose optimization by controlling generalized type I error and power while optimizing the sample size.
- The implementation of MERIT is simple, which only involve comparison of the observed number of toxicity and efficacy with prespecified decision boundaries.
- We have developed R shiny app on www.trialdesign.org to facilitate the application of MERIT design.
